

In Roman mythology $\mathcal{N e}$ ptune was the god of the Sea. He
is known as Poseidon in Greek mythology. The planet was probably named after the seagods be. cause of its deep blue colour. This is the symbol for Neptune:

Neptune is the eighth planet from the Sun and the fourth largest (6y size) of the nine planets. Neptune is smaller in size Gut it's heavier than Uranus.

Neptune's blue color is the re. sult of a gas called "methane" in its atmosphere. Like the other gas planets, Neptune has rapid winds trapped in "bands" of latitude and large storms. Neptune's winds are the fastest in the solar system, reaching $2000 \mathrm{~km} /$ hour!

At the time of Voyager's flyby, Nep.
 tune's most outstanding feature was the "Great Dark S pot" in the southern hemisphere. It was about half the size as I upiter's "Great Red Spot" - about 1 Earth would fit into it. Neptune's winds blew the Great Dark Spot we stward at 300 meters/second (700 mph)!

Voyager 2 also saw a smaller dark spot in the southern hemisphere and a small irregular white cloud that zipped around Neptune every 16 fours or so now. This feature is Known as "The Scooter."

 peared!Scientists think that it has either dissipated (like our storms do) or is currently being fidden by Neptune's atmosphere. Asso, $\mathcal{H S} \mathcal{T}$ discovered a newdarkspot in $\mathcal{N e p t u n e}$ 's northernfemisphere. $\mathcal{T}$ his shows that $\mathcal{N e p t u n e ' s ~ a t m o s p h e r e ~ c h a n g e s ~ r a p i d l y . ~}$
$\mathcal{N}$ eptune also fias rings. The Voyager 2 spacecraft showed scientists that $\mathcal{N e} p$. tune indeed has complete rings with bright clumps. Like Uranus and I upiter, $\mathcal{N}$ (eptune's rings are very dark and very faint. Scientists still haven't figured out what they are made of yet.

Lookfor Neptune! Neptune can be seen with binoculars (if you knowexactly where to look) but a large telescope is needed to see anything other than a tiny
 disk.
$\sim \mathcal{N e}$ (une is a giant gas planet which is most likely made up of various "ices" and rock.
$\sim \mathcal{N e p t u n e}$ has been visited by only one spacecraft, Voyager 2 on $\mathcal{A} u g 25$ 1989. Almost everything we know about $\mathcal{N}$ (eptune comes from this one visit.
$\sim \mathcal{D e}$ pending on how far along Pluto is in its orbit (path around the Sun), Neptune can be either the eighth or ninth planet. Pluto's or 6 it is kind of wacky, and it sometimes crosses infront of $\mathcal{N e}$ ptune. When Pluto does this, Neptune is Gefind Pluto - hence, it is the ninth plane $t$ for a sfort time.
$\sim \mathcal{N e}$ ptune has 8 known moons; 7 small ones and a large moon called "Triton."
